Foreword

Research is one of the main functions of the Institute for Population and Social Research, Mahidol University, and the publication of reports that strengthen our state-of-the art knowledge in population changes is an essential component of this process. This report entitled “Estimated Generation of Life Tables for Thailand of Five-Year Birth Cohorts : 1900 – 2000” by Pramote Prasartkul and Uthaithip Rakchanyaban is the latest in the Institute’s research publication series.

Professor Dr. Pramote Prasartkul has written a number of books, research reports and other publications in demography. His latest research report will surely make a significant contribution to our knowledge of Thailand’s demographic situation. Furthermore, the life tables will not only interest demographers but will also be of important use for other scientists in conducting their works.

Estimated Generation Life Tables for Thailand of Five-Year Birth Cohorts : 1900-2000

Introduction

It has been universally accepted that the life table is a powerful tool for the analysis of mortality and survivorship. The concept and technique of life table construction have been employed by a variety of specialists in a number of ways. Life tables are not only employed in the field of Demography, health scientists and actuaries always use them in their analyses. Life expectancy at birth, derived from the life table has become a well-known indicator of socioeconomic and health development of a population.

Life tables can be classified according to the reference year of the table into two types: period (or current) life table and cohort (or generation) life table.

- a) The period life table represents the combined mortality experience by age of the population in a particular short period of time, such as in a year or 3 years. The age specific death rates over a short period of time, usually obtained from cross-sectional survey data or vital statistics, are used to construct this type of table. The indicators derived from the period life table indicate the mortality of the population at that particular period of time.
- b) The cohort life table represents the mortality experienced by a particular birth cohort. The age specific death rates of that cohort from their birth through each consecutive age group in successive calendar years are employed to construct this type of table. Obviously, mortality data over a period of not less than 100 years are needed to complete a single table. Thus it is difficult, especially in countries without a long history of reliable vital statistics, to construct cohort life tables from actual mortality data. However, a cohort life table summarizes the mortality experience resulting from socioeconomic and health development over a lifetime of a particular birth cohort. This cannot be obtained from a period life table.

In Thailand, life tables commonly constructed are of the first type. Cohort life tables have never been calculated, which may be due to the lack of cohort mortality data. However, there should be cohort or generation life tables for the Thai population to introduce another dimension to the analysis of mortality change. Our attempt here is to construct a series of cohort life tables on the basis of synthetic data. The data used are estimated and projected mortality schedules by age group in consecutive years of birth cohorts of the Thai population.

Life tables for Thai population, cohort 1900 – 2000

The cohort life tables presented in this volume have been developed to represent hypothetical mortality and survivorship experiences of the Thai population born during the 20th century. These tables show various mortality and survival functions from birth of each cohort through each consecutive age group in successive calendar year. The birth cohorts are of every 5 years, starting from those born in 1900 to the last cohort born in 2000. Tables for male and female are provided separately.

Method of construction

Before the construction of the cohort life tables, the trends of ‘period’ life expectancies at birth (e_0) during the 20th and 21st century (1900 to 2100) were estimated and projected based on available period life tables available for the Thai population (Rungpitartangsi ,1974 & National Statistical Office, Report the Survey of Population change). It was assumed that the increase of e_0 followed a logistic function, with a lower limit at about 37 years during the first half of the 20th century and an upper limit at about 82 years during the last half of the 21st century. The trends for male and female were estimated separately. The graphs of life expectancies are shown in Figure 1, which display the estimated and projected trend of the mortality transition in Thailand during mid 20th to mid 21st century.

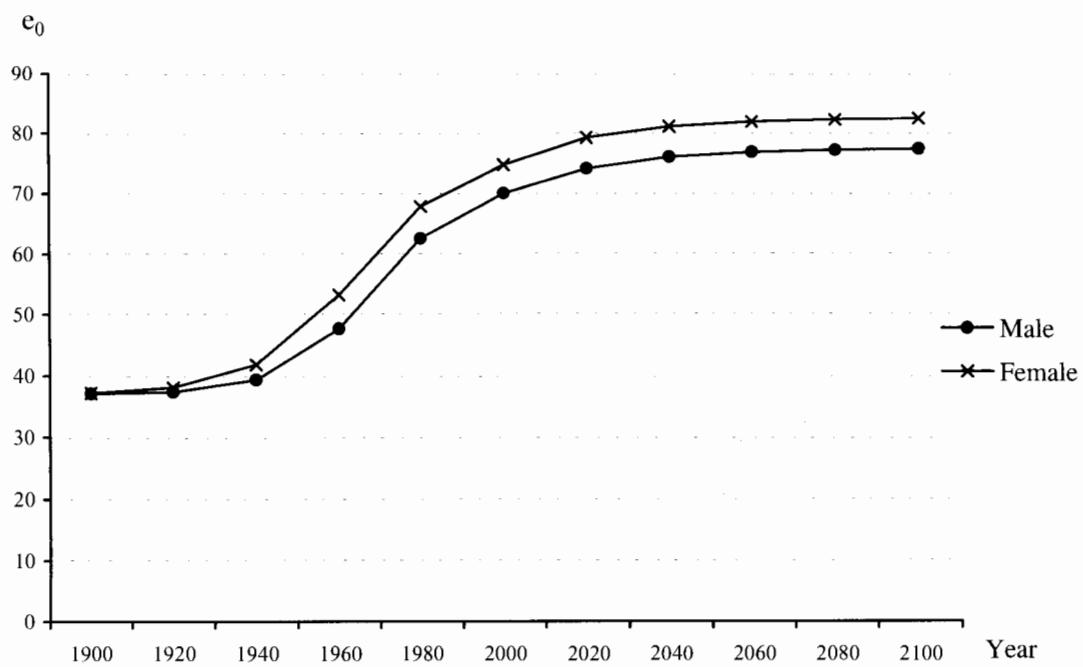

Figure 1. Trend of e_0 from period life tables, 1900 – 2100, male and female

Table 1. Estimated period life expectancies at birth, 1900 – 2100

Year	Male	Female	Both sexes	Year	Male	Female	Both sexes
1900	37.06	37.22	37.14	2005	71.30	76.45	73.81
1905	37.10	37.33	37.21	2010	72.40	77.54	74.91
1910	37.16	37.49	37.32	2015	73.32	78.45	75.83
1915	37.25	37.73	37.48	2020	74.09	79.21	76.58

1950	42.22	46.34	44.23	2055	76.71	81.75	79.17
1955	44.58	49.50	46.98	2060	76.86	81.90	79.32
1960	47.62	53.17	50.32	2065	76.98	82.02	79.44
1965	51.24	57.12	54.11	2070	77.08	82.11	79.54
1970	55.18	61.06	58.05	2075	77.16	82.19	79.61
1975	59.05	64.70	61.81	2080	77.23	82.25	79.68
1980	62.50	67.83	65.10	2085	77.28	82.30	79.73
1985	65.31	70.35	67.77	2090	77.32	82.34	79.77
1990	67.43	72.28	69.80	2095	77.36	82.37	79.80
1995	68.96	73.71	71.28	2100	77.38	82.39	79.83
2000	70.01	74.73	72.31				

The e_0 of each 5 year birth cohort was used for linear interpolation to derive the probability of dying by age (nq_x) from the Regional Model Life Tables developed by Coale and Demeny (1966). The West model was used. In addition, the model life tables revised by Coale and Guo (1989, 1991) were applied to extend the last age group to 100 years old. The nq_x from those period life tables were then rearranged by age and calendar year to represent the mortality schedule at corresponding ages of each birth cohort. The graphic presentation in Figure 2 explains this procedure. The following are examples:

${}_1q_0$ of the cohort born in 1900 is the ${}_1q_0$ in the 1900 period life table,
 ${}_5q_5$ of the cohort born in 1900 is the ${}_5q_5$ in the 1905 period life table,
 ${}_5q_{90}$ of the cohort born in 1900 is the ${}_5q_{90}$ in the 1990 period life table.
and ${}_5q_{100}$ of the cohort born in 1900 is equal 1.

The nq_x of all age groups of each birth cohort were then used to calculate other functions of the life tables, namely nD_x , nM_x , L_x , nL_x , T_x and e_x .

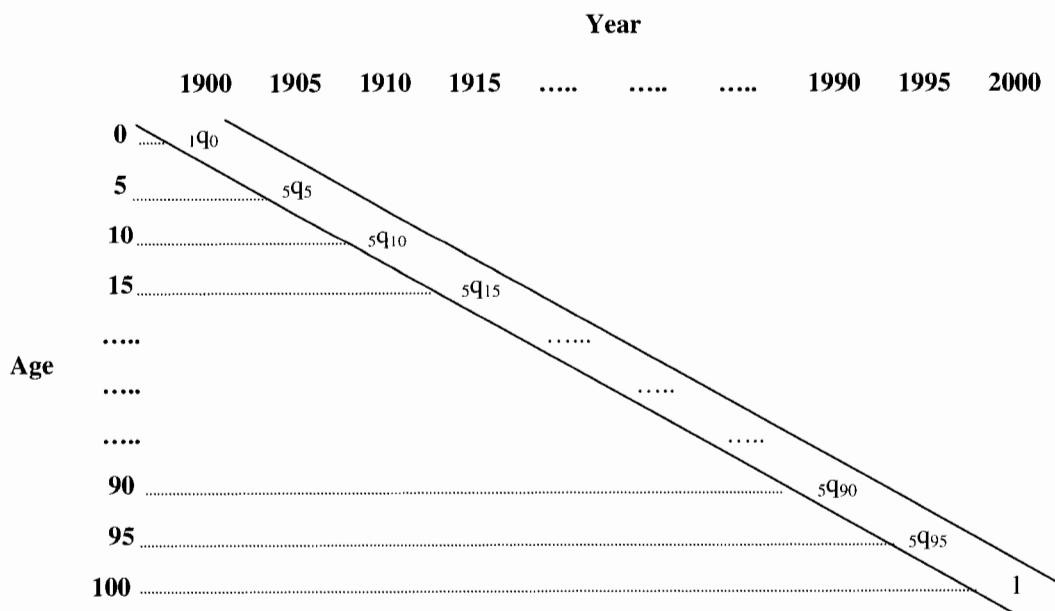

Figure 2. Transformation of nq_x from period to cohort life tables

The time frame of cohort life tables included in this volume.

The life tables compiled in this volume were constructed for cohorts born every five year, i.e. those born in 1900, 1905, 1910, to the last birth cohort of 2000. The year of each table represents the mid-point of a five-year interval. For example, the table for the cohort of 1910 could be applied for those born during mid --1907 to mid --1912. Arithmetically, the values of any function for those born in any year can be interpolated from the life tables provided.

The values of nq_x and e_x from the period life tables in the corresponding birth year are shown in the last two columns for comparison.

Conclusion

The cohort life tables included in this volume are provided a resource for researchers interested in studying the mortality transition of the Thai population. The life tables provide a wealth of information that can be used in exploring how the socio-economic development has affected the mortality experiences of cohorts born in the twentieth century.
